

Flash Redemption: roll out to Blue & Silver

AeroVanti loyalty leadership · 2026-09 · 12-week randomised test, months 19–21

+2.7 pp

redemption-rate lift (pooled, $p \approx 2 \times 10^{-6}$)

+3.2 pp

re-weighted to the member base

$\approx +1.5$ pp

durable, after the launch bump decays

Blue + Silver

where the effect is real (interaction $p = 0.0007$)

Recommendation. Roll out Flash Redemption to **Blue and Silver**. Hold Gold and Platinum at the current 10,000-point threshold — no measured benefit there. Keep a revenue-per-member guardrail and a redemption-depth guardrail live for the first two quarters of rollout.

Did it work?

Yes. Lowering the minimum redemption threshold (10,000 → 3,500 SkyPoints) and adding a low-cost reward catalog raised the 12-week redemption rate from 12.8% to 15.5% — a **+2.69 pp** lift, highly significant ($z = 4.7$, $p \approx 2 \times 10^{-6}$). Randomisation is clean (no sample-ratio mismatch; every pre-period covariate balanced). Re-weighted to the real member base (68% Blue), the lift is **$\approx +3$ pp**.

But not for everyone — and not all of it lasts

Tier	Control	Treatment	Lift (pp)	95% CI	Verdict
Blue	6.1%	9.9%	+3.8	[+2.5, +5.0]	clear
Silver	10.8%	13.0%	+2.2	[+0.1, +4.2]	yes, marginal
Gold	19.4%	21.9%	+2.5	[−0.6, +5.6]	not significant
Platinum	35.6%	35.1%	−0.5	[−5.2, +4.2]	no effect

The arm × tier interaction is significant ($LR \chi^2 = 17.0$, $p = 0.0007$): the effect really does shrink from Blue to Platinum. Blue — members sitting just below the old threshold with nowhere to spend — gain the most (+62% relative). Top-tier members already redeem freely and gain nothing.

About **half the headline lift** is a **launch novelty bump** that decays over the window (weekly-increment trend -0.044 pp/week, $p = 0.017$). Plan the business case on the **durable** $\approx +1.5$ – 2 pp.

Is it safe? (guardrails)

Guardrail	Effect	Read
Flight revenue per member	-0.09% (n.s.)	no harm, but the test is <i>too small to prove</i> non-inferiority — keep monitoring

90-day disengagement	-2.0 pp (p = 0.001)	favourable — the causal echo of "redeemers stay"
Net point-liability cost / member	-R\$0.81 (n.s.)	slightly favourable — more redemption draws down points that would expire
Value per redeeming member	-R\$19 (-6.8%, p = 0.001)	watch — Flash drives more but <i>shallower</i> redemptions

Why this matters — the hoarding problem

Only **32% of active members have ever redeemed** (25% of Blue); just 9% redeemed last quarter. Two-thirds hold enough points — they simply never start. The co-brand card issues **55% of all points**, to members with no flight attached and the weakest reason to engage. The unredeemed-points liability is **R\$25.7M** gross (R\$15.4M breakage-adjusted), and the recognised figure swings **±R\$2.6M per 10 pp** of the breakage assumption. Members who redeem lapse at 10.6% vs 21.1% for never-redeemers (-6.0 pp after adjustment) — redemption is a retention lever, not just a marker.

Next steps. (1) Roll out to Blue + Silver. (2) Add a co-brand-card redemption nudge — the highest-leverage adjacent move. (3) Run a breakage cohort study when a full lot lifetime of data exists — the liability estimate risk is material. (4) Extend the post-rollout window to turn the 90-day disengagement signal into a 12-month retention number.

Synthetic, seed-generated data (SEED 20260902). Every figure is computed on two tracks (pandas + DuckDB) with a parity assertion — `python data_analysis/parity/run_all.py`. The true experiment effect is not in any document; it lives only in `etl/config.py` and was detected from the data.
